## 1. Review

- Scope of Identifiers
- Pointer
- Call by reference
- Recursive Functions

## 2. This week's Tasks + Hint

# Identifiers

In C++, variable, function, type, or other kind of object is called an identifier.  
C++ has several rules to follow when naming identifiers.

- Keywords(ex. cout, int, include etc...) are reserved and cannot be identifiers.
- Identifiers may consist only of upper and lower case letters, numbers and characters.
- Identifiers cannot begin with numbers.
- C++ distinguishes between upper and lower case letters.

# Scope of identifiers

## Local variable

: After being used only in declared blocks, it becomes meaningless.

## Global variable

: It is declared outside the main and can be called from anywhere after it is declared.

# Scope of identifiers

```
#include <iostream>  
using namespace std;
```

```
int num;
```

→ Local / global

```
int main() {  
    double count;  
    return 0;  
}
```

→ Local / global

```
double power(){  
    double x;  
    return x;  
}
```

→ Local / global

# Scope of identifiers

```
Int main( ) {  
    int count = 0;  
}
```

```
Float sub(void) {  
    int count = 20;  
}
```

If the blocks are different, it doesn't matter if the names are the same.

# Pointer – the address of operator (&)

```
#include <iostream>
using namespace std;

int main() {
    int x = 5;
    cout << x << endl;
    cout << &x << endl;

    return 0;
}
```

5  
0xffff000bdc

# Pointer – the dereference operator (\*)

```
#include <iostream>
using namespace std;

int main() {
    int x = 5;
    cout << x << endl;
    cout << &x << endl;
    cout << *&x << endl;

    return 0;
}
```

```
5
0xffff000bdc
5
```

# Pointer

A pointer is a variable that stores a memory address, not a value.

## Declaring a pointer

```
int *ip;  
double *dp;
```

-> Type + \* + variable name;

# Assigning a value to a pointer

```
#include <iostream>
using namespace std;

int main() {
    int value = 5;
    int *ptr = &value;

    cout << &value << endl;
    cout << ptr << endl;

    return 0;
}
```

0xffff000bd4  
0xffff000bd4

# Call by reference

# Recursive function

```
void countNum_recursive(int num)
{
    if (num == 1)
    {
        cout << " Num : " << num << endl;
        return;
    }
    else
    {
        cout << " Num : " << num << endl;
        countNum_recursive(num - 1);
    }
}
```

```
void countNum_for(int num)
{
    for (int i = num; i > 0; i--)
    {
        cout << " Num : " << i << endl;
    }
}
```

```
void countNum_while(int num)
{
    while (num > 0)
    {
        cout << " Num : " << num << endl;
        num--;
    }
}
```

It is a code that outputs the process of reducing the number of inputted numbers one by one.

# Recursive function - factorial

< Recursive code >

< Previous code >

```
int factorial(int num) {  
    int result = 1;  
  
    for (int i = 2; i <= num; i++)  
        result *= i;  
  
    return result;  
}
```

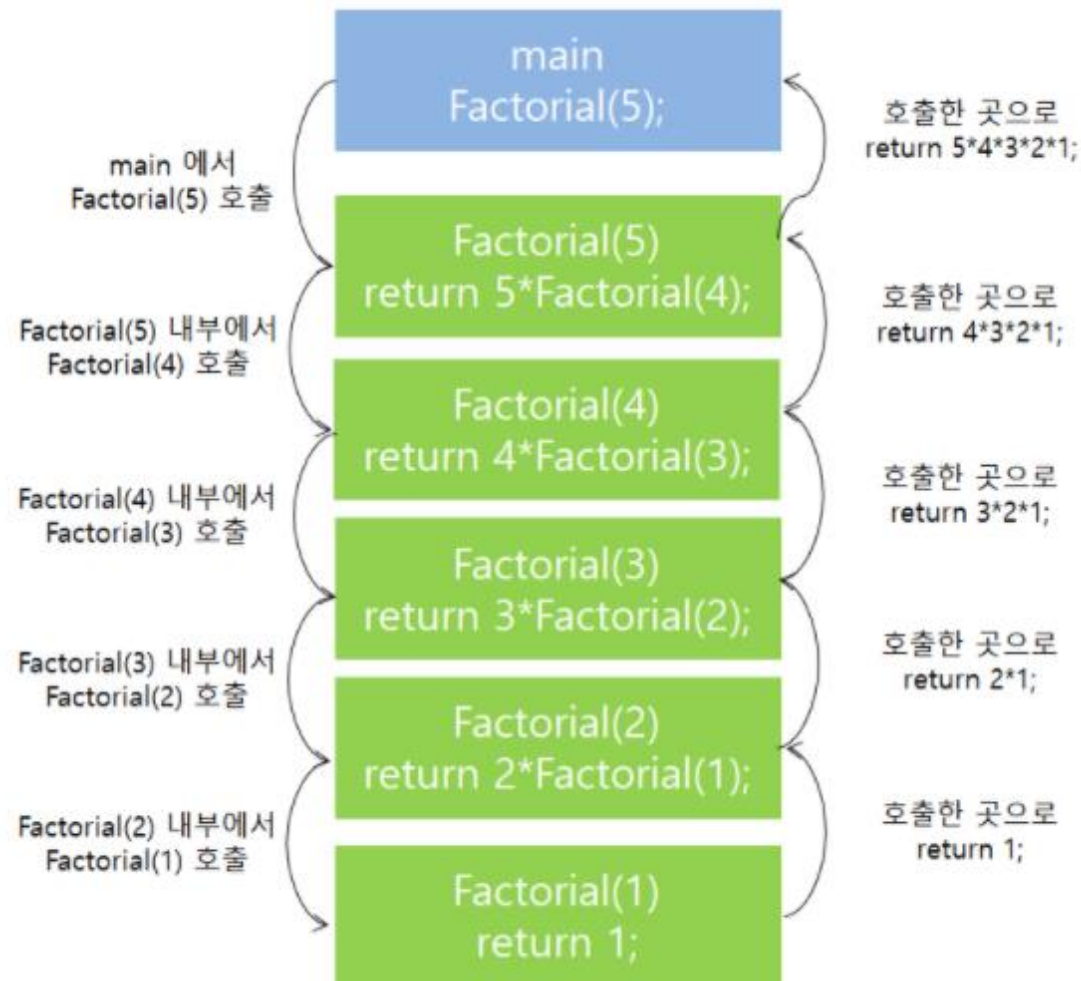

5! 값 = 120

```
#include <iostream>  
using namespace std;  
  
int main() {  
    int num = 5;  
  
    cout << num << "! 값 = " << factorial(num) << endl;  
  
    return 0;  
}  
  
int factorial(int num) {  
    if (num == 1) {  
        return 1;  
    }  
  
    return num * factorial(num - 1);  
}
```

# Recursive function - factorial

# Task 1 : print binary

---

Write the code that outputs in binary format using recursive functions.

★ Declare the following functions:

```
void print_binary(int x);
```

★ Hint. Divide by two and print the rest in reverse order until the quotient is zero.

## Task 2 : factorial

---

Write a factual code using the recursive function.

★ Declare the following functions:

```
double factorial(int);
```

★ Hint. Add a declaration of the function from the content covered in the lecture.

## Task 3 : gcd(greatest common measure)

---

Write a code that uses Euclidean protection to obtain the maximum common number.

$$\begin{aligned}\text{gcd}(x, y) &= \text{gcd}(y, x \% y) \\ \text{Gcd}(x, 0) &= x\end{aligned}$$

★ x is bigger than y

## Task 4 : pointer

---

Answer the questions related to the pointer.

```
int i = 1; int k = 2; int *p1; int *p2;  
p1 = &i; p2 = &k; p1 = p2; *p1 = 3; *p2 = 4;  
cout << i;
```

## Task 5 : call by reference – swap

---

Write a swap function using call by reference.

The swap function works by exchanging the values of two variables.

★ Declare the following functions:

```
void swap( ,  );
```

How should we fill it out?
